

Experiment 18 :

Implement a Simple First-Order Predicate Calculus (FOPC) Parser Using Python

Code:

```
expression = input("Enter FOPC expression: ")
predicate = expression[:expression.index("(")]
arguments = expression[
    expression.index("(")+1:
    expression.index(")")]
]
print("Predicate:", predicate)
print("Arguments:", arguments.split(","))
```

Output

```
expression = input("Enter FOPC expression: ")
predicate = expression[:expression.index("(")]
arguments = expression[
    expression.index("(")+1:
    expression.index(")")]
]
print("Predicate:", predicate)
print("Arguments:", arguments.split(","))
```

... Enter FOPC expression: Loves(John,Mary)
Predicate: Loves
Arguments: ['John', 'Mary']
